

Realistic modeling of sub-hourly flexibility and energy storage in resource planning

ESIG 2023 Fall Technical Workshop

October 25, 2023

La Jolla, California

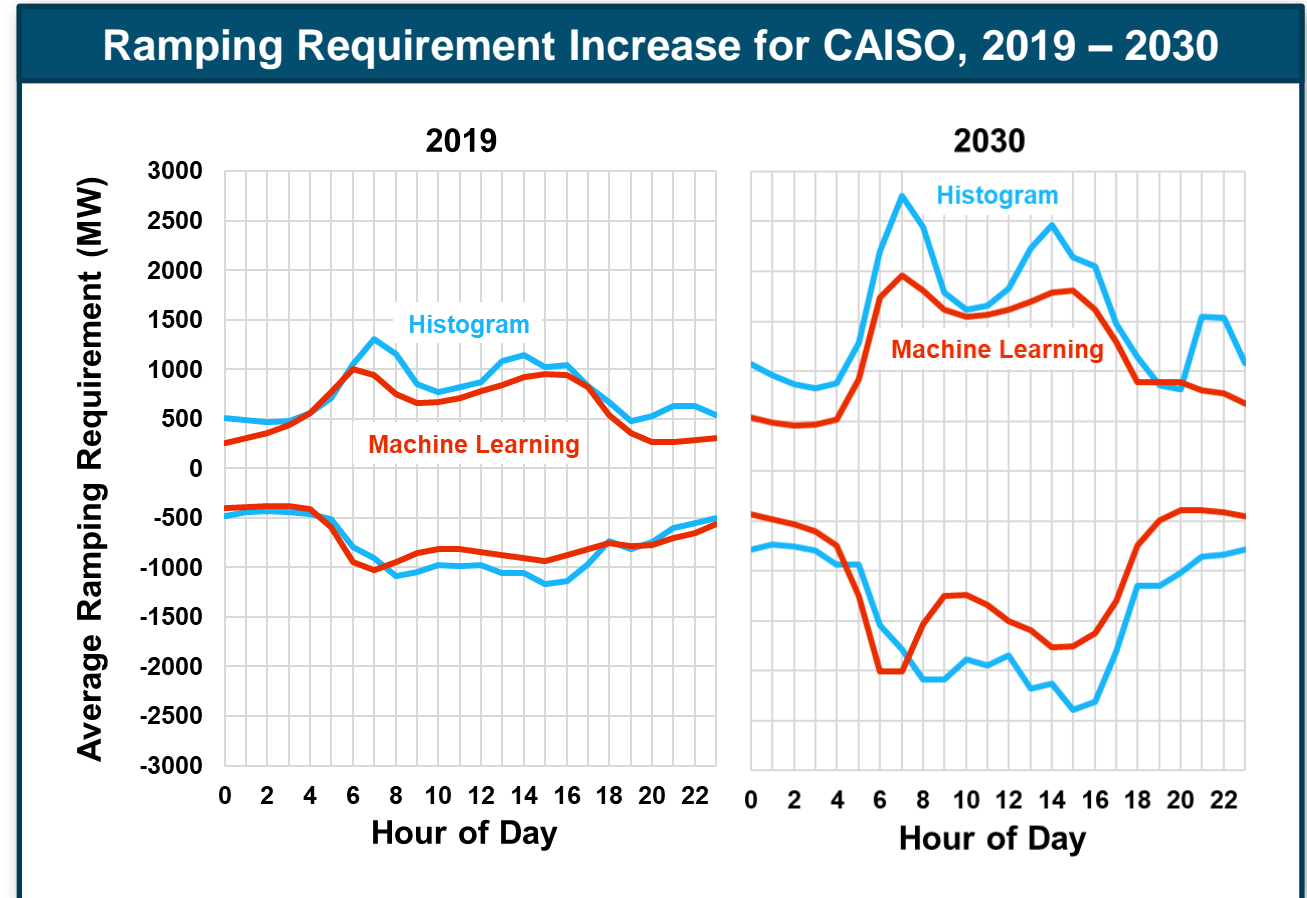

Energy+Environmental Economics

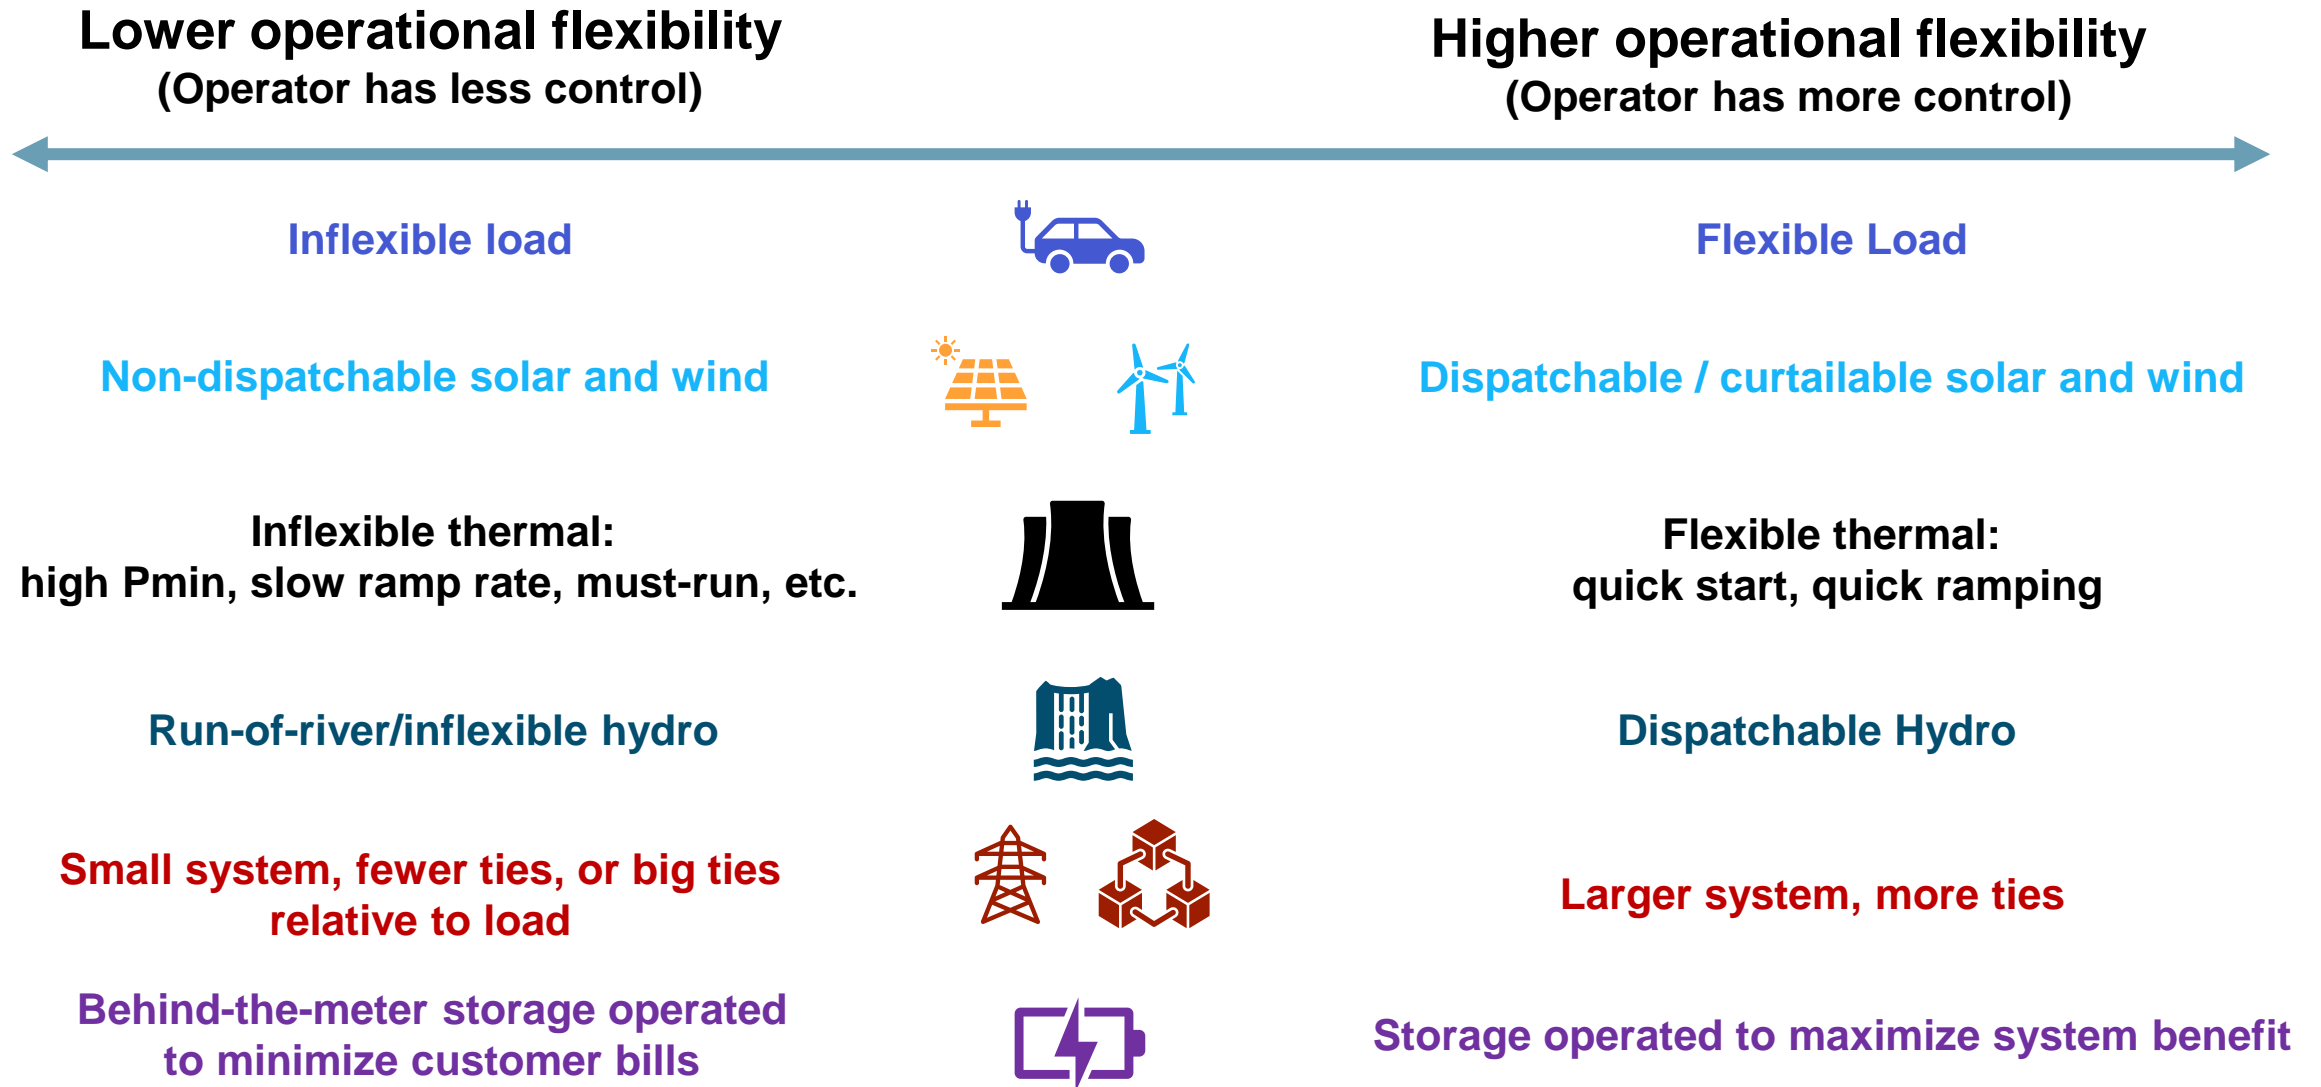

Arne Olson, Senior Partner

Need for grid services will grow with higher penetrations of wind and solar generation

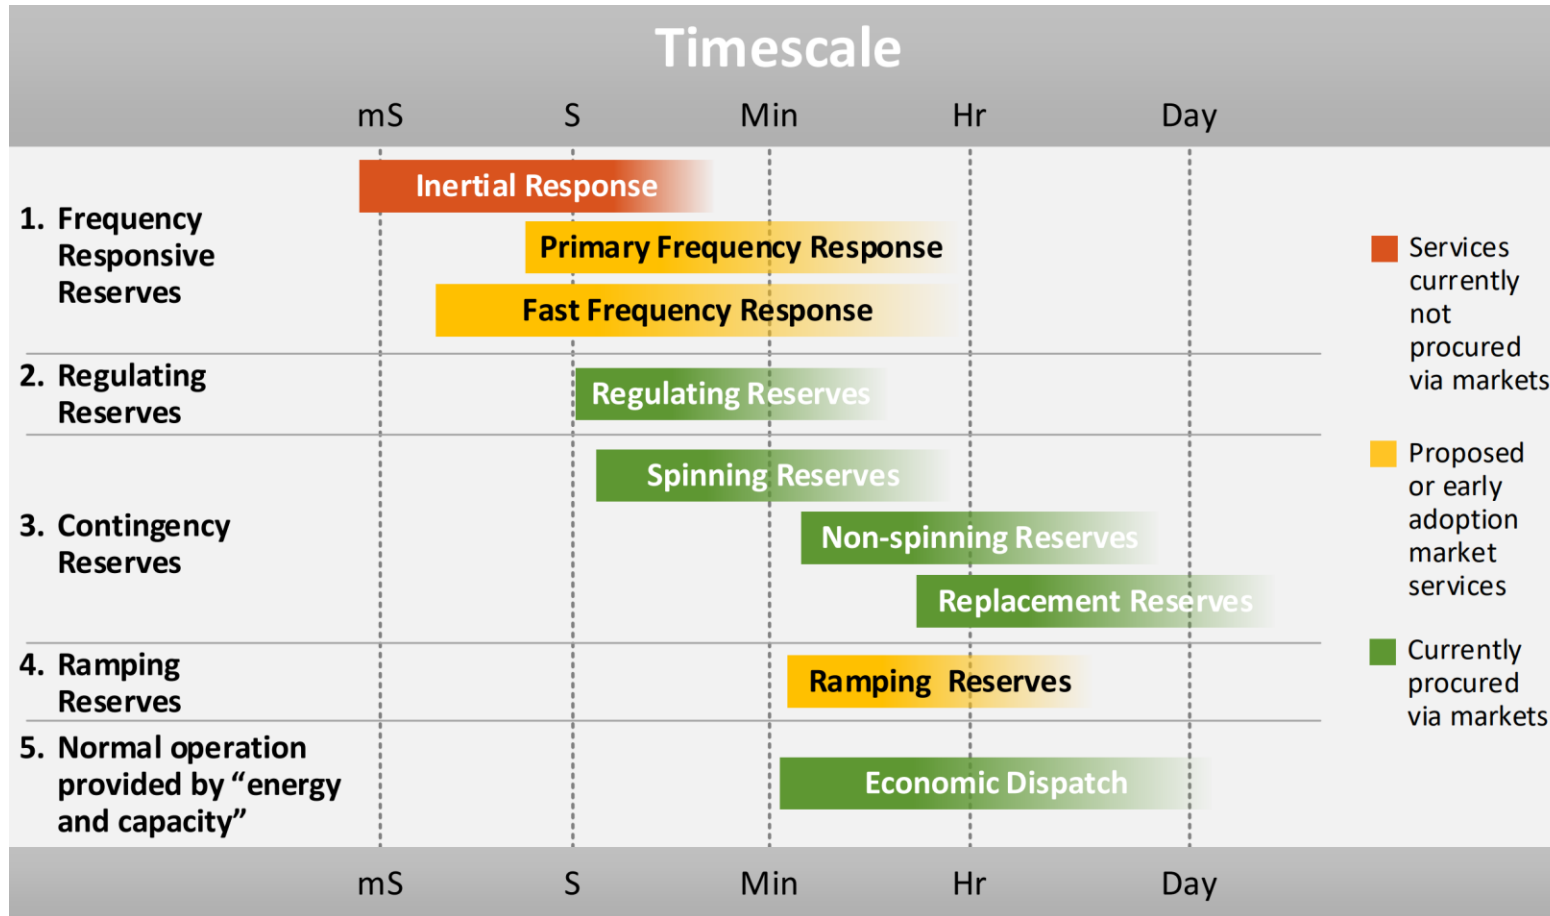

- + Grid operators have always balanced variability and uncertainty in demand and supply using ancillary services
- + The need for grid services will grow as wind and solar increase due to **increased variability and forecast errors**
- + The need for grid services will also become more dynamic as grid conditions change with the weather

Operational Flexibility Drivers

Reserve types and timescales

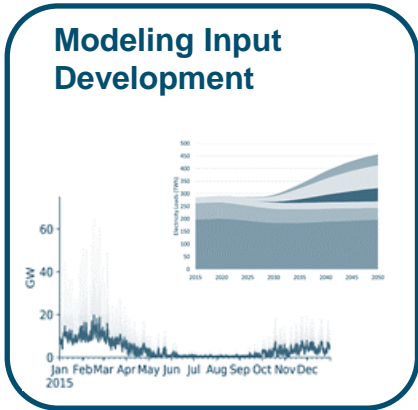

All reserves are held in one timeframe to prepare for another timeframe

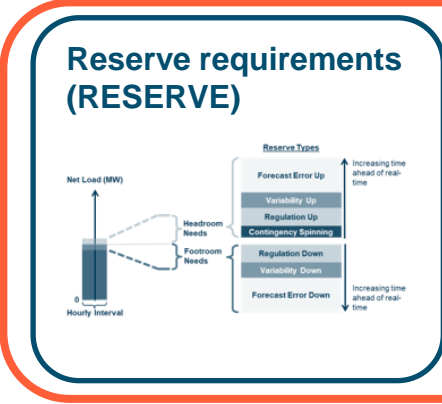

Reserves are used or released when needed during grid operations

Portfolio planning framework

Inputs: resource and fuel costs, policy goals, resource potential, etc.

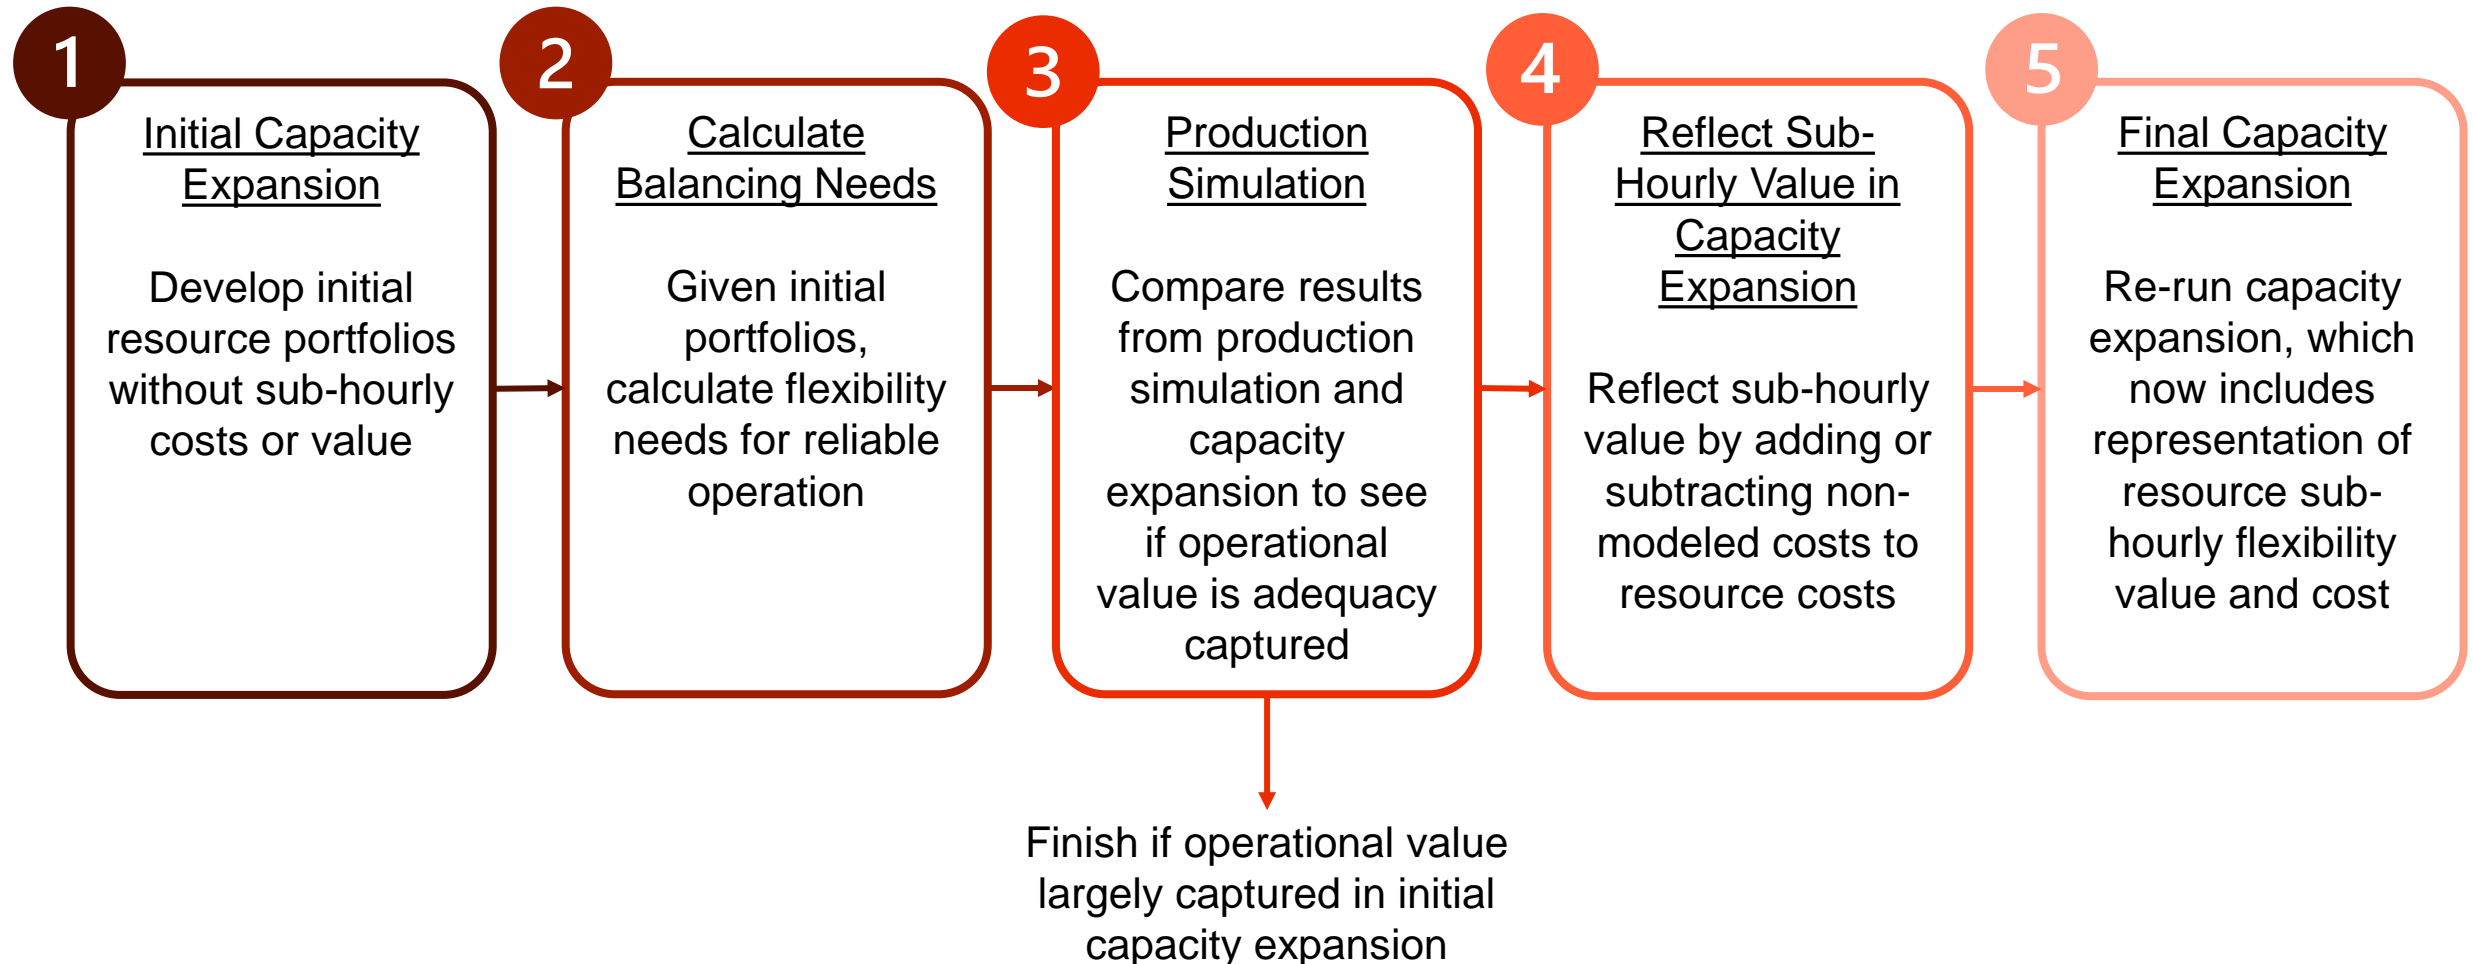

- Additional Related Studies:**
- Avoided Costs
 - DER optimization
 - Distribution needs for EV adoption
 - Bulk Transmission needs
 - Resilience to large disruptions

Final recommendations, builds, costs, emissions

IRP Filing

Workflow for valuing operational flexibility in planning

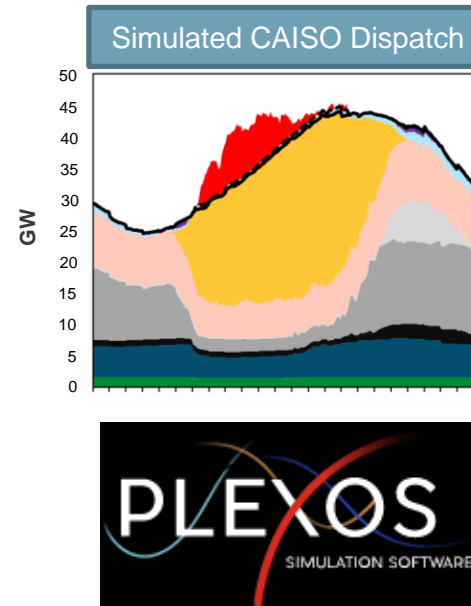

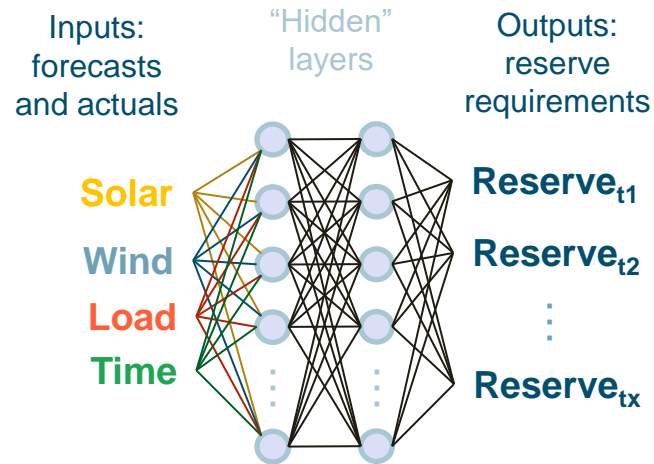

E3's RESERVE tool uses machine learning for dynamic operating reserve calculation

Machine learning generates reserve needs using artificial neural network

PLEXOS production simulation of CAISO system validates operability

Summary and CAISO Comparison

- Compare machine learning reserves to CAISO current practice
- Estimate cost, GHG and curtailment savings

+ **E3 Team:** Adrian Au + Charles Gulian + Saamrat Kasina + Jimmy Nelson + Patrick O'Neill + Arne Olson + John Stevens + Yuchi Sun + Vignesh Venugopal + Mengyao Yuan

+ **ARPA-E PERFORM program** provided grant funding

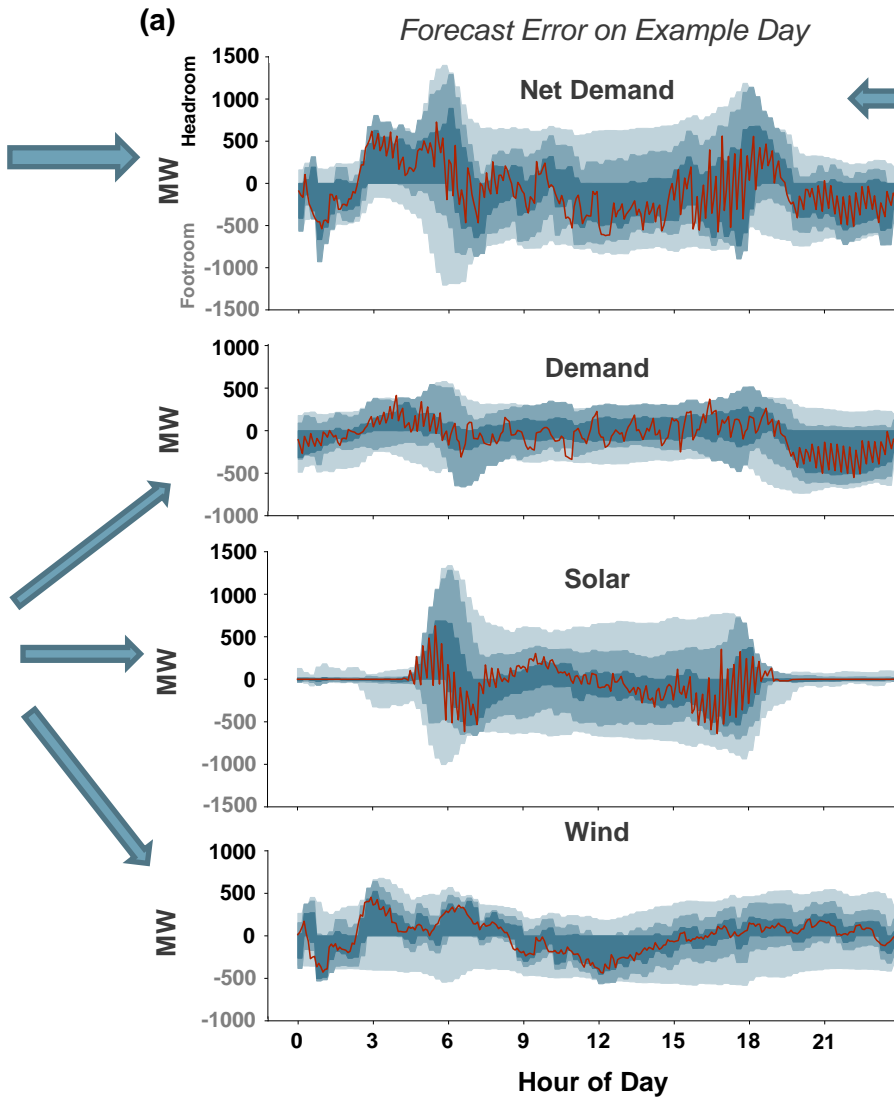

+ **CAISO** was our industry partner

Probabilistic uncertainty from machine learning reserves

Net load forecast error...

is assembled from the individual constituent components

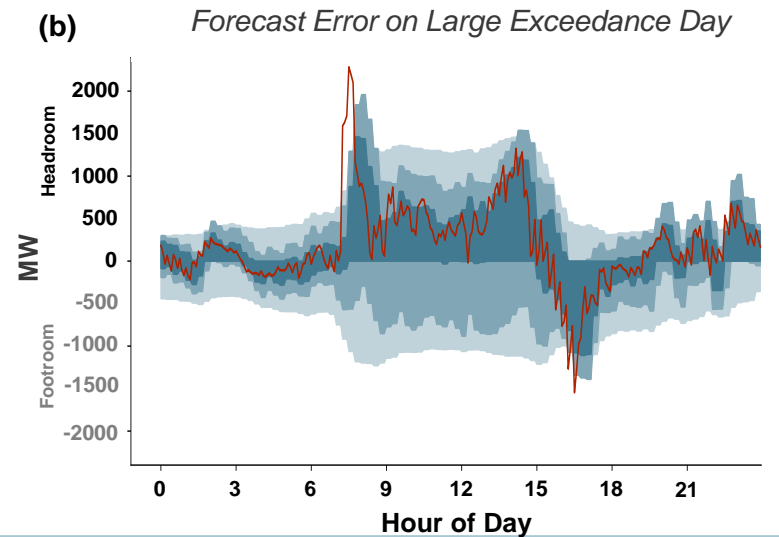

Dynamic based on grid conditions...

Legend

More dynamic when grid conditions are more dynamic...

Multi-stage production simulation captures sub-hourly operational flexibility needs and benefits

Scheduling
Timeframe

Operational flexibility decreases

Forecast accuracy increases

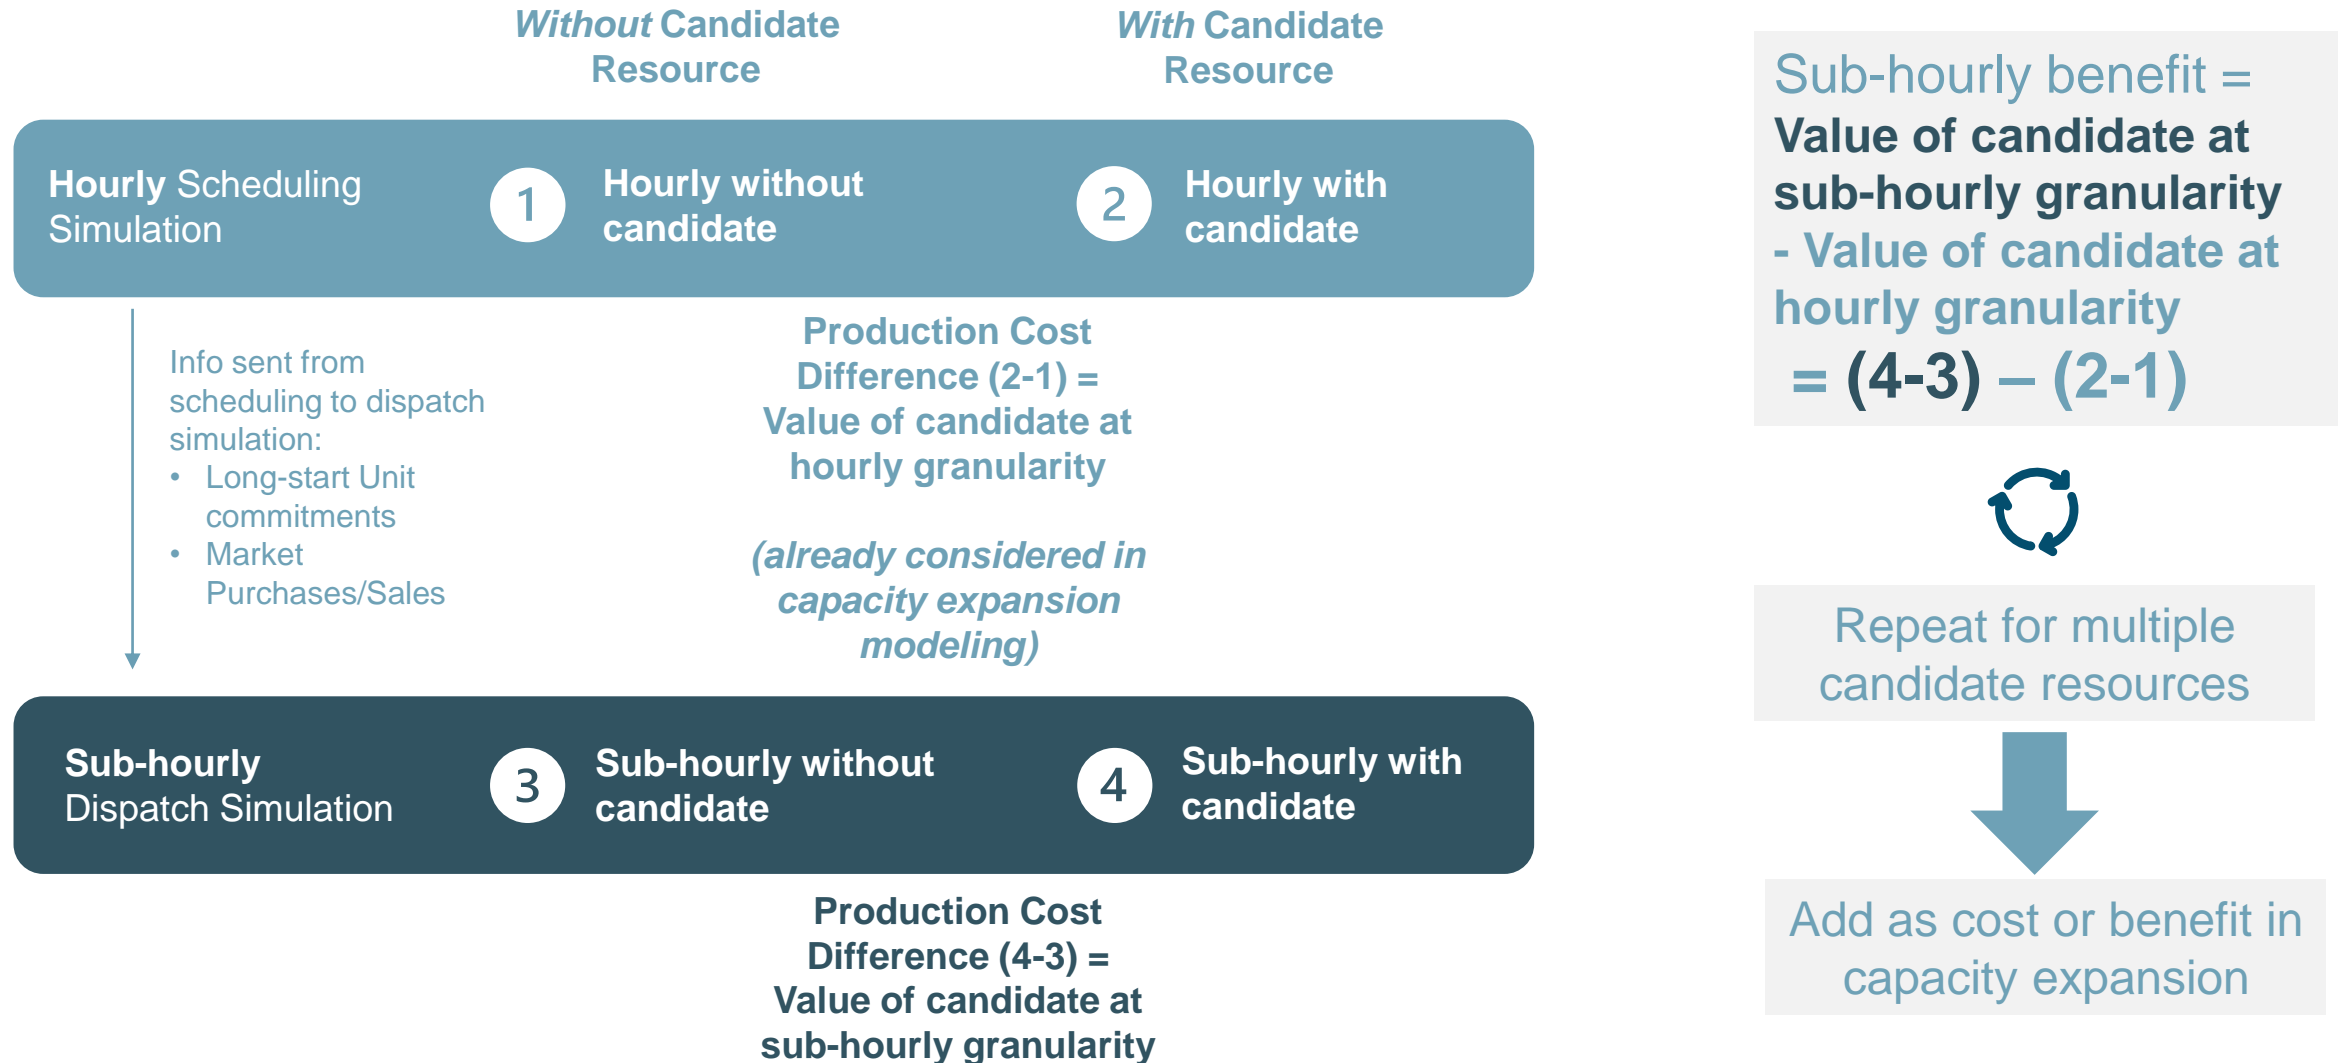

PLEXOS production simulation model mimics scheduling and dispatch decisions that system operators make on many timeframes

Operational Reserves

Upward
Downward

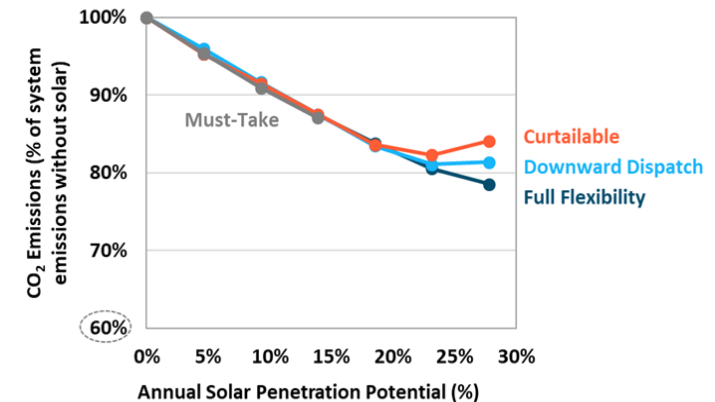

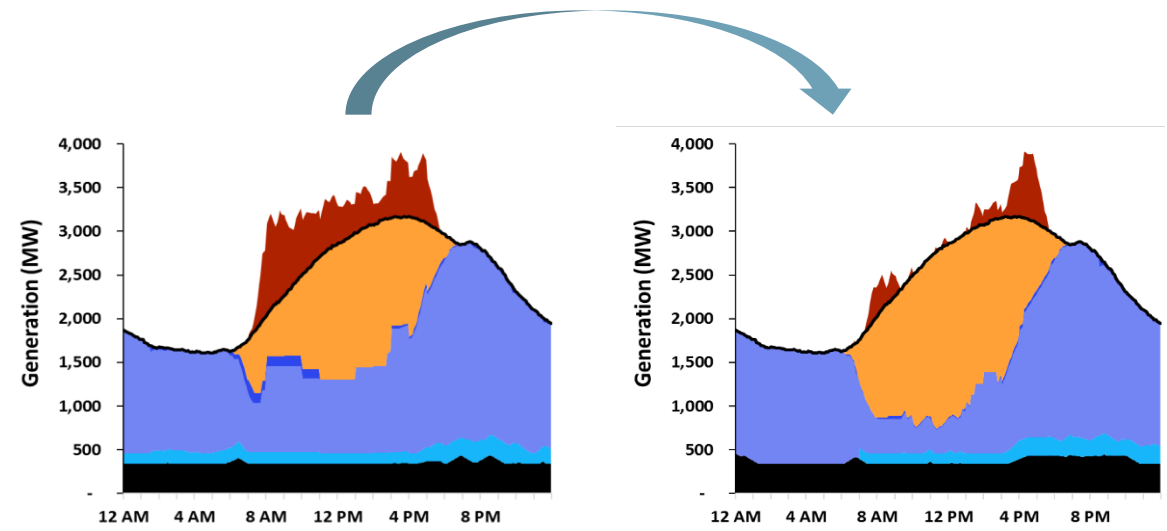

Isolating sub-hourly operational flexibility value to supplement capacity expansion modeling

Case study: explore tradeoffs in thermal cycling vs. renewable curtailment

- + Lowering output from thermal units during heavy solar production hours can decrease solar curtailment and thereby make solar more economical
- + BUT cycling thermal units can increase wear and tear
- + Also, turning plants off can decrease the flexibility of the system to respond to higher net loads
- + Production simulation can explore the tradeoff between increased thermal cycling and renewable curtailment, while simultaneously exploring the reliability of different operational strategies

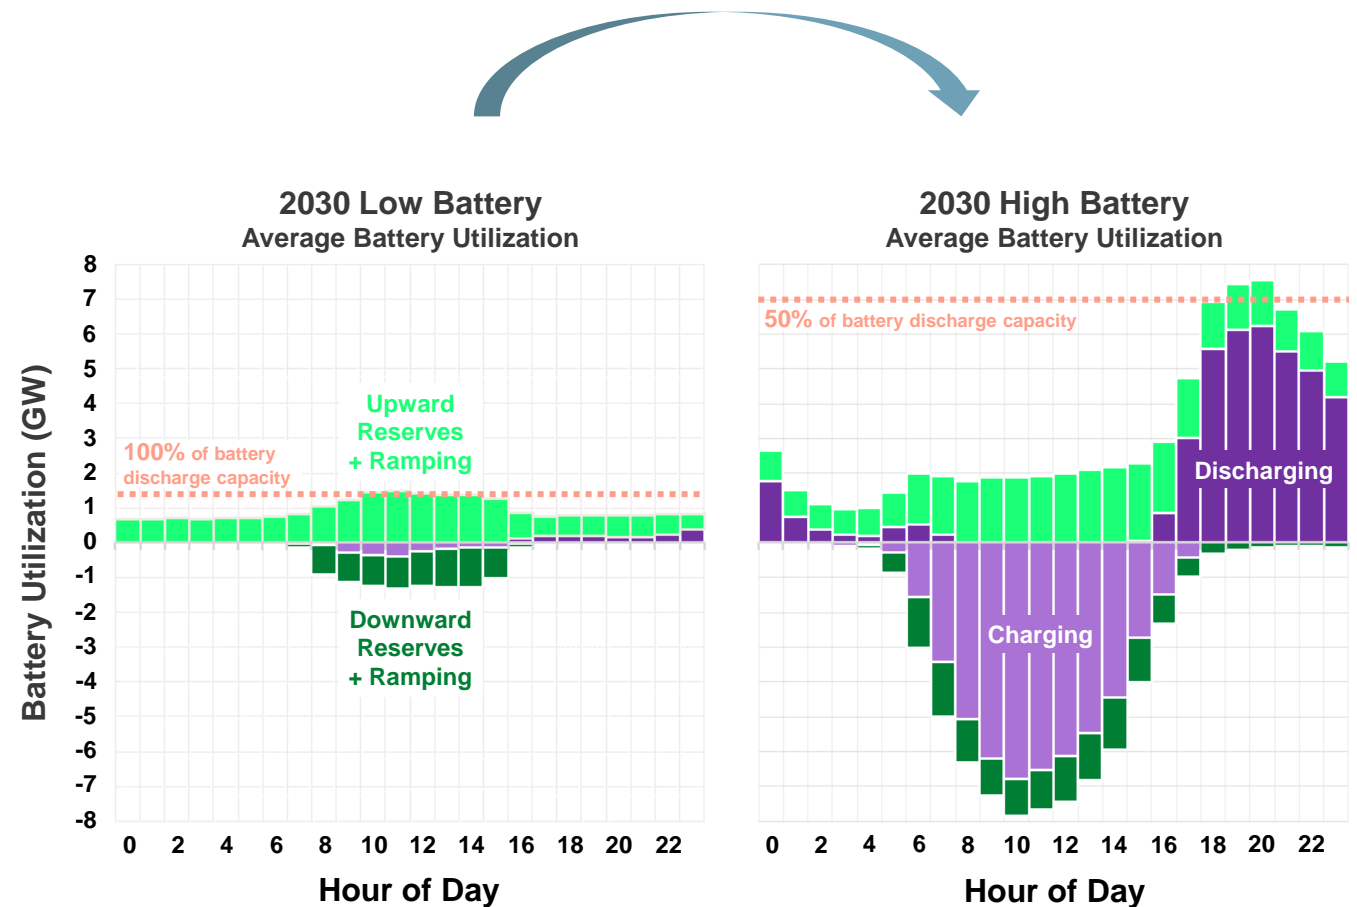

Lower thermal generation enables higher uptake of solar

Case study: value of batteries

- + **Production cost modeling can identify the most economic way to operate batteries**
 - Timing of batteries providing energy arbitrage, regulation, spinning reserve, flexible ramping
- + **Can inform how to manage battery state of charge in operations**
- + **Can quantify battery cycling**
 - Helps to understand the impact of battery contract terms about number of cycles allowed

Optimal use of batteries evolves as more storage is added to the system

Capacity expansion modeling includes options to increase flexibility, for a cost

Planning models include options to increase flexibility... at a cost

Increase load flexibility

Make solar or wind curtailable

Build, retire or retrofit thermal plants to improve flexibility

Improve hydro flexibility

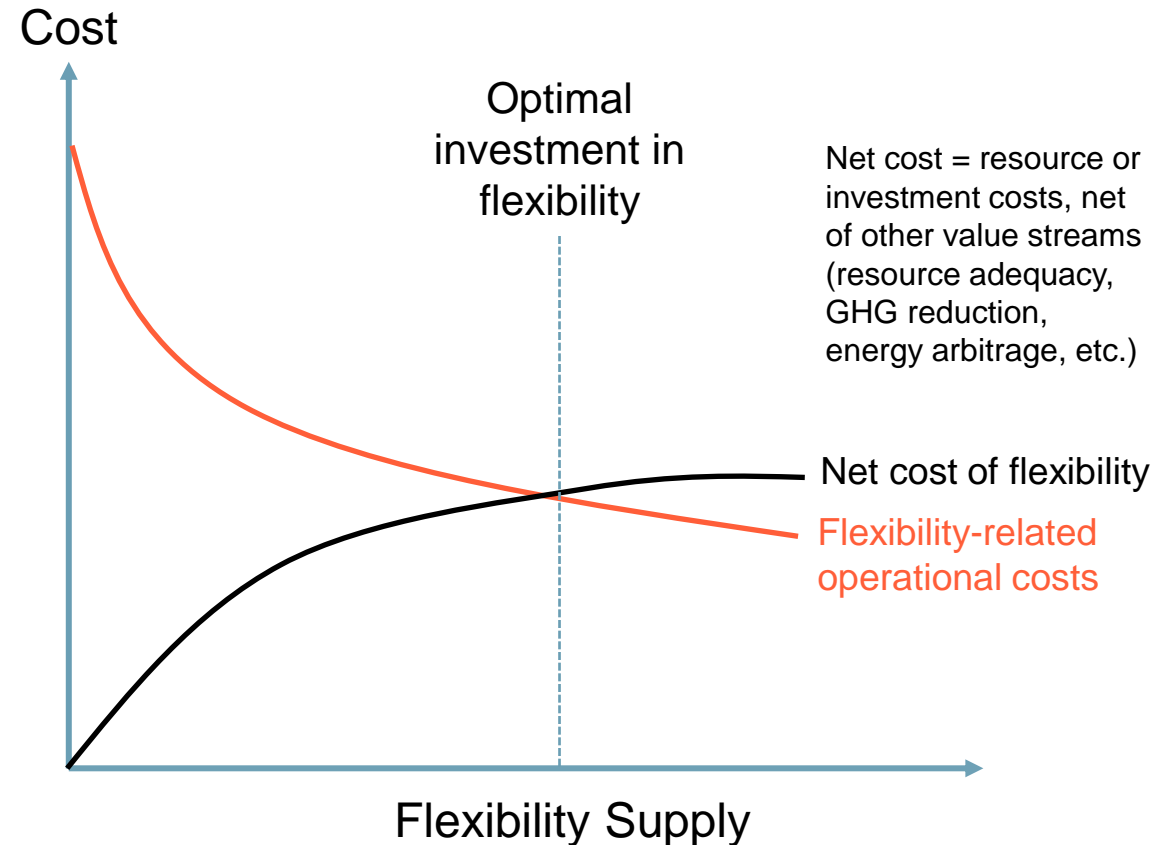

Add battery storage capacity

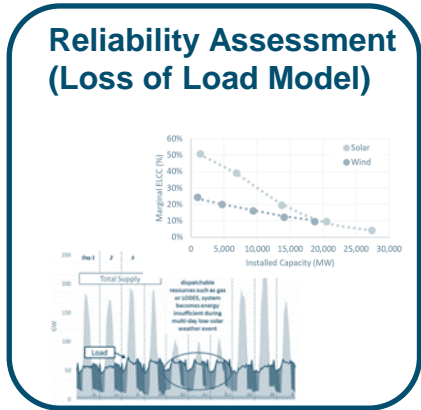

Build or upgrade ties to other systems

*Theoretical Flexibility cost curve:
Dependent on system conditions and the resource portfolio*

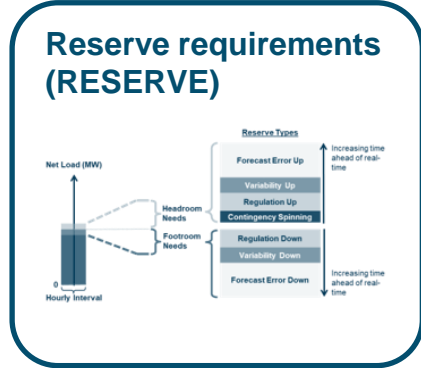

Portfolio planning framework

Inputs: resource and fuel costs, policy goals, resource potential, etc.

- ### Additional Related Studies:
- Avoided Costs
 - DER optimization
 - Distribution needs for EV adoption
 - Bulk Transmission needs
 - Resilience to large disruptions

Final recommendations, builds, costs, emissions

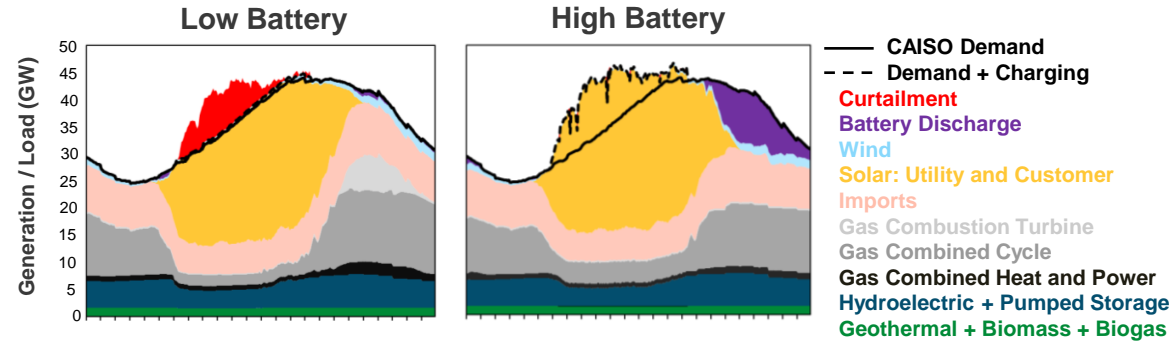

IRP Filing

Higher battery penetration adds flexibility and reduces reserve prices

2030 Example Summer Day

Generation

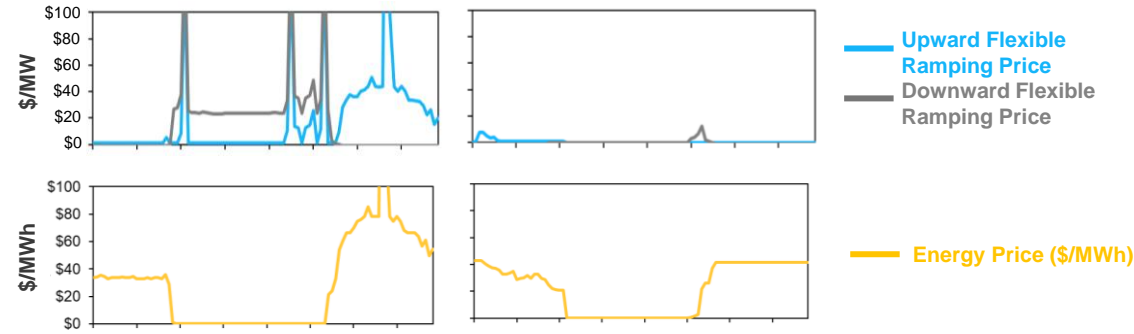

With few batteries, curtailment is abundant

More batteries use solar that would have been curtailed to reduce peaker dispatch

Reserve and Energy Prices

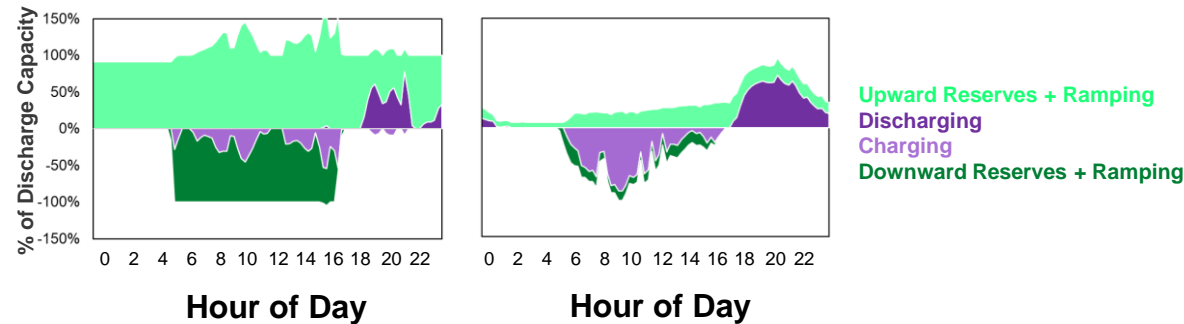

While system flexibility is low, reserve prices stay high

With more batteries, flat energy prices in the day and night give the batteries enough flexibility to provide reserves at low or zero cost

Battery Operations

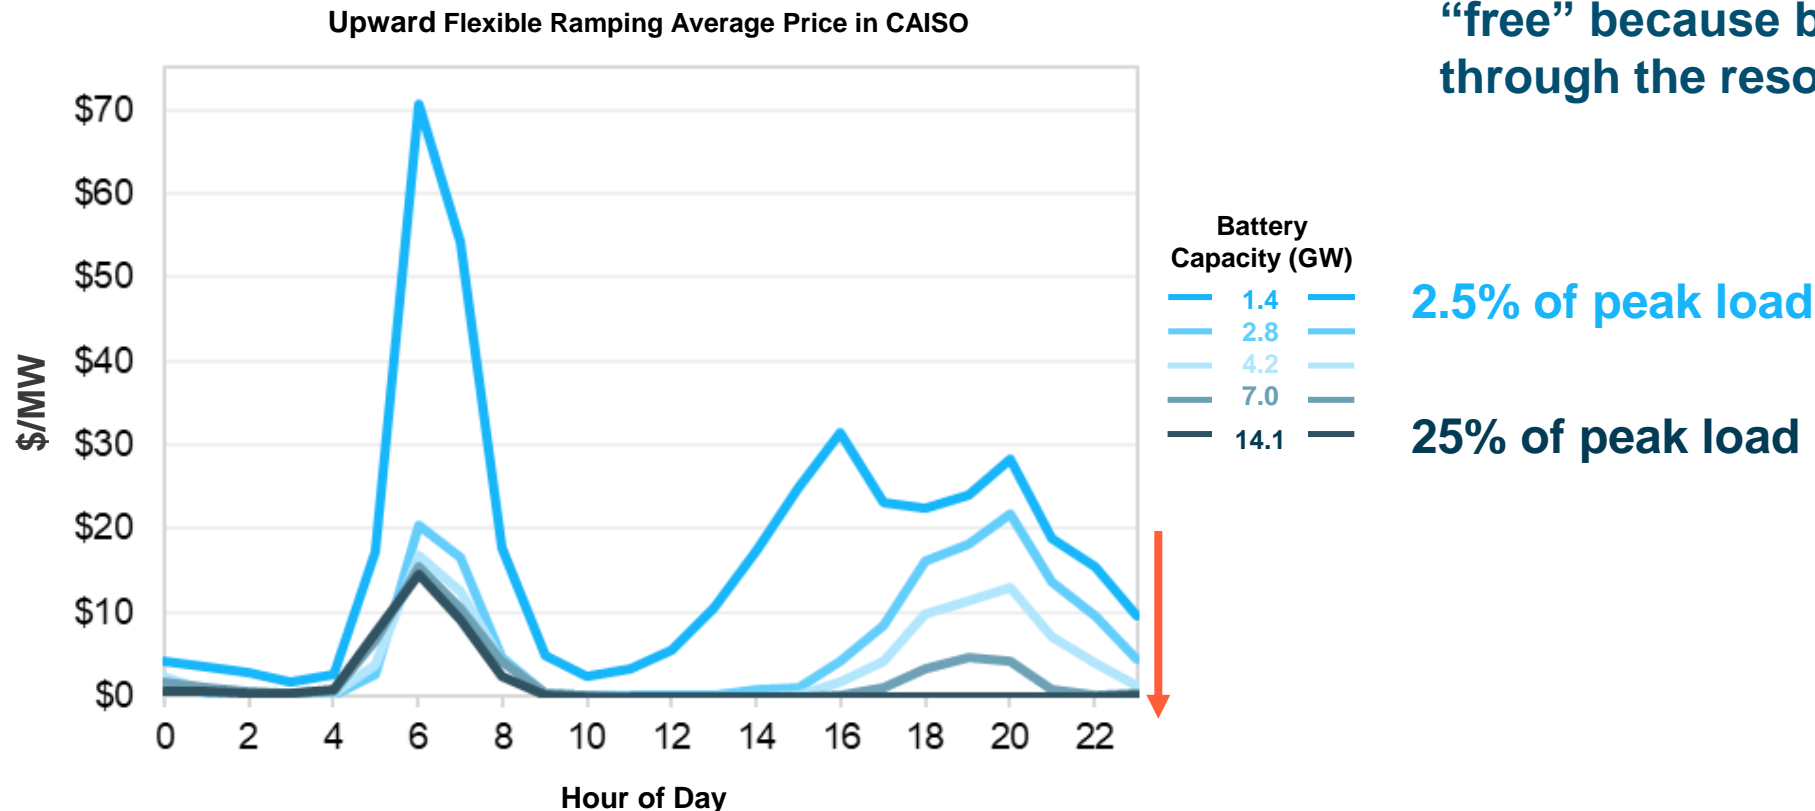

With few batteries, batteries focus on providing reserves

With more batteries, they can provide most of the reserves and also perform energy arbitrage

Higher battery penetration adds flexibility and reduces reserve prices

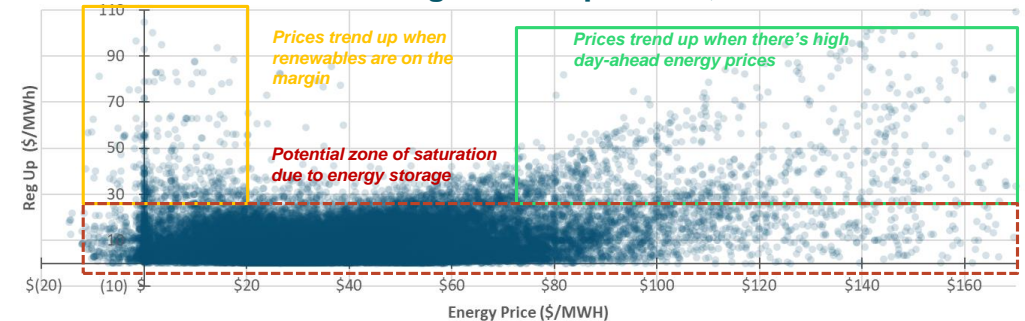

- + Increasing flexibility from batteries leads to decreasing reserve prices
- + In California, this grid flexibility is “free” because batteries are “paid for” through the resource adequacy need

For organized markets, operational studies are replaced by ancillary service price forecasts

- + Organized markets provide the grid services needed for operations, at a price
- + Utilities in organized markets need to be concerned not with operations of their own system, but rather the price of grid services from the market
- + Grid service prices will change as the resource mix changes

CAISO Regulation Up Prices, 2017-2022

CAISO Regulation Down Prices, 2017-2022

CAISO Spinning Reserve Prices, 2017-2022

Ancillary service markets are small and prices are dynamic with changes to the resource mix

- + Storage participation has already reduced average AS prices in the CAISO market today
- + Frequency of low ancillary service prices rapidly increases between 2023-2025 as storage further saturates the market
- + Reg down saturates more slowly as seen in current market trends

Thank you!
