

Decarbonization of US Energy: Electrification and Beyond

Geoffrey J. Blanford, Ph.D.
Senior Technical Executive, Energy Systems and Climate Analysis

ESIG Virtual Workshop
April 14, 2020

U.S. National Electrification Assessment (USNEA)

- Economy-wide assessment:
 - Residential, commercial, industrial and transport
- Modeling with endogenous technology adoption from end-user perspective
- Customer decisions integrated with detailed electricity supply model
- Progressive and Transformation scenarios include economy-wide carbon pricing
- Just the beginning... kickstart to EPRI's Electrification Initiative

US-REGEN Modeling Platform

Electric Generation

Detailed representation of:

- Energy and capacity requirements
- Renewable integration, transmission, storage
- State-level policies and constraints

Synchronized

Hourly Load,
Renewables,
and Prices

Model Outputs:

Economic equilibrium
for generation, capacity,
and end-use mix

Emissions, air quality,
and water

Energy Use

Detailed representation of:

- Customer heterogeneity across end-use sectors
- End-use technology trade-offs
- Electrification and efficiency opportunities

Potential for Efficient Electrification Varies by End-Use Application

US 2015 Final Energy Break-Out

Efficient Electrification: Reference

Efficient Electrification: Transformation

8760 Load Shape by Load Category in Base Year

Reference Projections Reflect Electrification / Efficiency

8760 Aggregate Load Shape in Base Year

Electrification Drives up Winter Peak

Active management of EV charging and space conditioning can reduce peak load by up to 5 GW in North Carolina

50% participation of households in load management programs enables most of the peak reduction benefit

Contributions to future peak demand in New York

What are the limits of electrification?

- For many direct uses of fossil fuel, electricity is the first-best alternative low-carbon fuel:
 - Light-duty vehicles
 - Space heating in milder climates
 - Water heating and other building uses (including cooking)
 - Non-road and short-haul MD/HD vehicles (e.g. buses, delivery)
 - Some applications in industry and long-haul heavy transport
- Electrification is more difficult in a few key applications:
 - Space heating in the coldest climates
 - Certain industrial processes
 - Certain transport applications, e.g. long-haul aviation

Opportunities for Electrification of End-Use Energy

Significant Electrification, but Not Everywhere

Potential Non-Electric Low-Carbon Fuel Demand

The “frontier” of electrification is uncertain, but inevitably, some energy service demand will be more economically met with a non-electric low-carbon fuel.

As a first cut, we can roughly approximate potential non-electric low-carbon fuel demand as a fraction of residual non-electric demand in the USNEA Transformation scenario.

The result is a rough order-of-magnitude estimate of the scale of low-carbon fuels demand of ~10 quads.

This can be compared to potential scale of bioenergy and hydrogen supply.

How does 1 quad of end-use demand for electrolytic H2 affect the electric sector? Simulation for WECC

- Impacts on capacity/generation mix (with a \$100/tCO₂ price):
 - More solar + **batteries**
 - Reduces NGCC and GT capacity/energy/emissions
 - Increases nuclear (i.e. Palo Verde) capacity factor 53% → 76%
 - Decreases wind/solar curtailment:
 - Wind: 6% → 3%
 - Solar: 9% → 3%
- Decreases (wholesale) electricity price by ~5%
- Electrolysis has ~60% capacity factor / avg. elec price of \$30/MWh
 - Translates to \$2.25/kg LCOH (or \$19/mmbtu), *before* delivery
- Introduces much more variability / ramping / operational challenges

Mountain-South \$100/tCO2 Scenario Example Dispatch

Mountain-South \$100/tCO₂ + Nele H₂ Demand

Import

Key Takeaways

- Technological improvements are making electrification an economical choice in several key sectors (especially LDVs), drives efficiency, lower emissions, and changing load patterns
- Opportunities for flexibility value (especially vehicle charging)
- Barriers to adoption remain
- Electrification doesn't make sense in all applications (even with a carbon price) → low-carbon fuels, e.g. hydrogen
- Electrolytic “green” hydrogen does have synergies with low-carbon electric generation in terms of lower costs, better asset utilization, but also increases demand for batteries, could fundamentally change how electric system is operated

Together...Shaping the Future of Electricity
