## When wind power forecasting becomes difficult

### **Challenges in extreme conditions**

- Effect of precipitation when dust and sand have decreased output with up 15%
- Risk of cut-out at high wind speed
- Risk of steep ramps when weather patterns are changing
- Effect of complex terrain (mountains) which is not captured adequate in weather models
- Icing on wind turbines
- ....and more

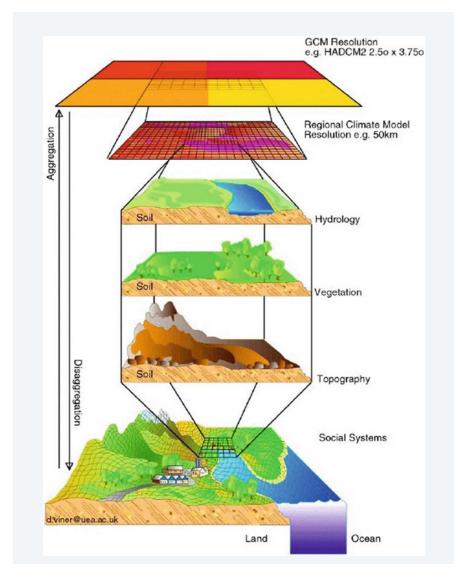

## Wind speed downscaling in complex terrain

### Why use downscaling?

- In complex terrain NWPs\* do not capture the wind speed with adequate precision
- Leading to "lower than normal" wind power generation forecast precision
- An alternative to resource intensive/expensive meso scala modelling

### How to perform downscaling

- Based on data-mining/deep-learning techniques
- Based on NWPs grid around farm
- Data-mining on a large set of candidate parameters from a number of NWPs
- Principle component analysis used to identify and prioritize parameters

#### NWP: Numerical Weather Prediction

## Wind speed downscaling in complex terrain

#### Analyzed & categorized per farm, month & NWP

#### **Reduction of forecast error**

- -: -2.5% to -0.5%
- =: -0.5% to 0.5%
- +: 0.5% to 2.5%
- ++: 2.5% to < 5.0%
- +++: >5.0%

#### Perform well on all farms except two:

- Open terrain, where the benefits are limited
- Small tree-covered hill well-performing already

#### Challenges

- A black box is a black box
- Can identify correlations, which can not be explained physically
- NPW model changes can result in sudden performance degradation
- Very CPU intensive
- Requires 6-12 months of historical data
- Requires a good dataset from the farms

#### V02 to address some of these challenges!

## Icing on wind turbines

### The issue with icing on turbines is...

- Significantly reduce output in part of the year for customers in North America & Scandinavia
- Does not only effect the period itself, but will also impact model calibration and forecast accuracy in a period after the event
- Not many turbines have ice detection equipment - and it is expensive

### ...that forecasting is difficult...

- Analysis show that forecasting yields too many falls positive and get the timing wrong
- Standard weather models do not capture enough details to model icing event
- Applying meso scala models tuned for ice forecasting does not improve things much
- Local conditions are just really complicated to model and therefore also to predict

## Icing on wind turbines

### ...so we took a different approach

- Online detection of icing & estimation of effect
- Forecast magnitude and duration of event
- Post-processing of power forecast to predicted icing effect

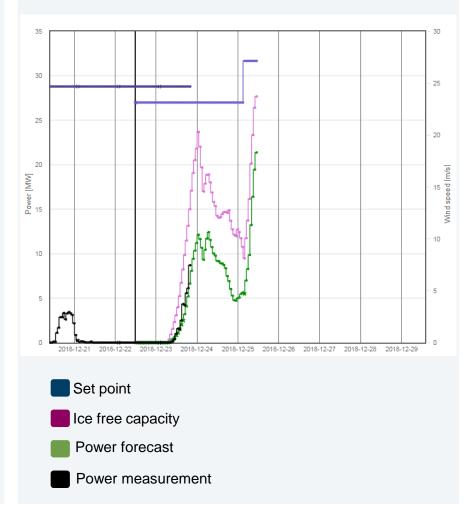

### V01 - 2013

- Tracking "status" of farm and if threshold met, classify as icing event
- Evaluate individual event without taking uncertainty into account
- Noise in bottom and top of power curve

#### V02 - 2019

- Introduction of state space model
- Uncertain events only get small weights
- Fine tuning of weights for fundamental model and real time calibration model
