

EPRI Solar Forecasting Trial

Will Hobbs, PE
Senior Research Engineer
Southern Company R&D

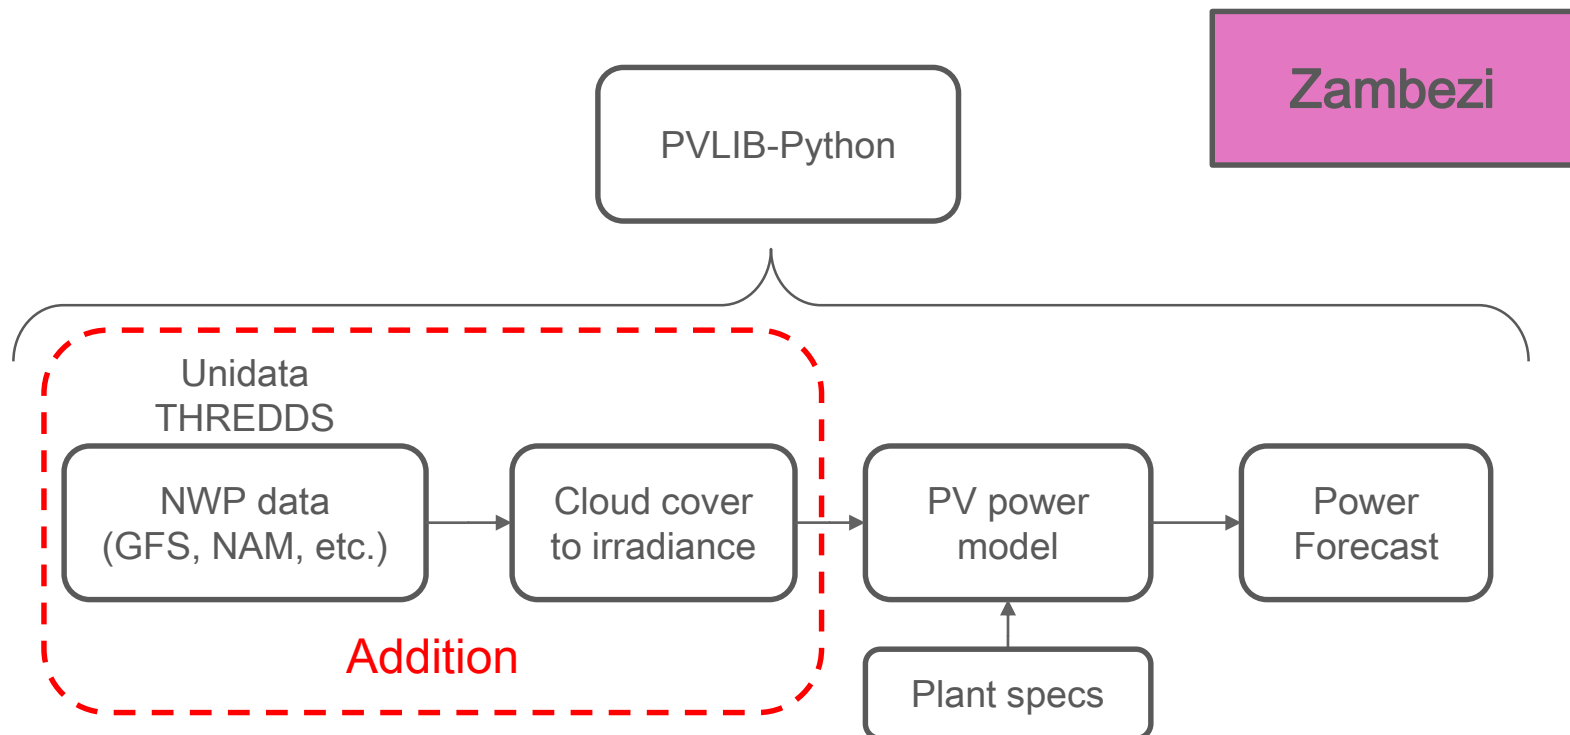

Trial project overview

- 2nd phase of ongoing EPRI project (Aidan Tuohy presented other results at earlier UVIG meeting)
- 12 vendor forecasts (not necessarily commercial)
- 6 month period
- 4 plants in 2 regions
- Emphasis on day-ahead
 - Novel “baseline” forecast

Baseline Forecast: PVLIB-Python

- Persistence would not be a good baseline for day-ahead
- New forecast tool developed by University of Arizona for this project
- Open source addition to PVLIB-python

INITIAL RESULTS

(still in draft form)

Forecast Skill Index

FSI Index = $([R1]+[R2]) / (100+(MAPE + RMSPE + WMAPE)/300)$

where $R1 = (NFI - MAPE_RANK) / (NFI - 1) * 50$

and $R2 = (NFI - VMAPE_RANK) / (NFI - 1) * 50$

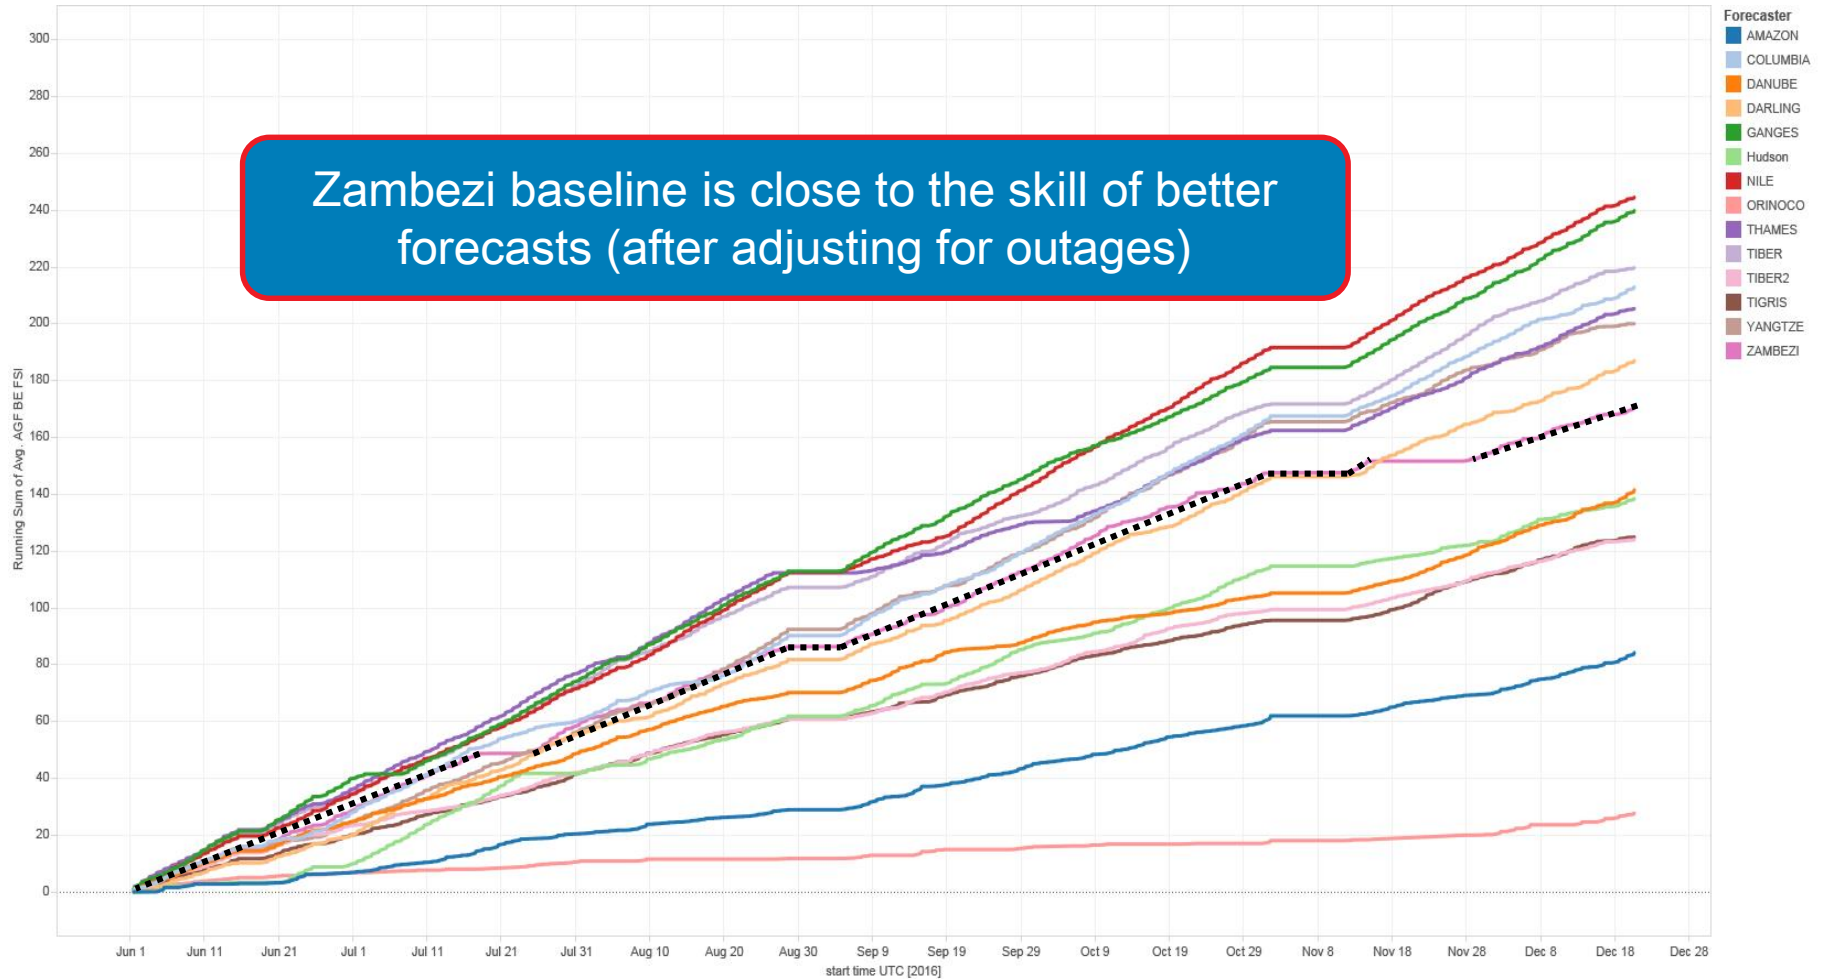

Higher is better - Max value of 1.0

Cumulative FSI (SE site)

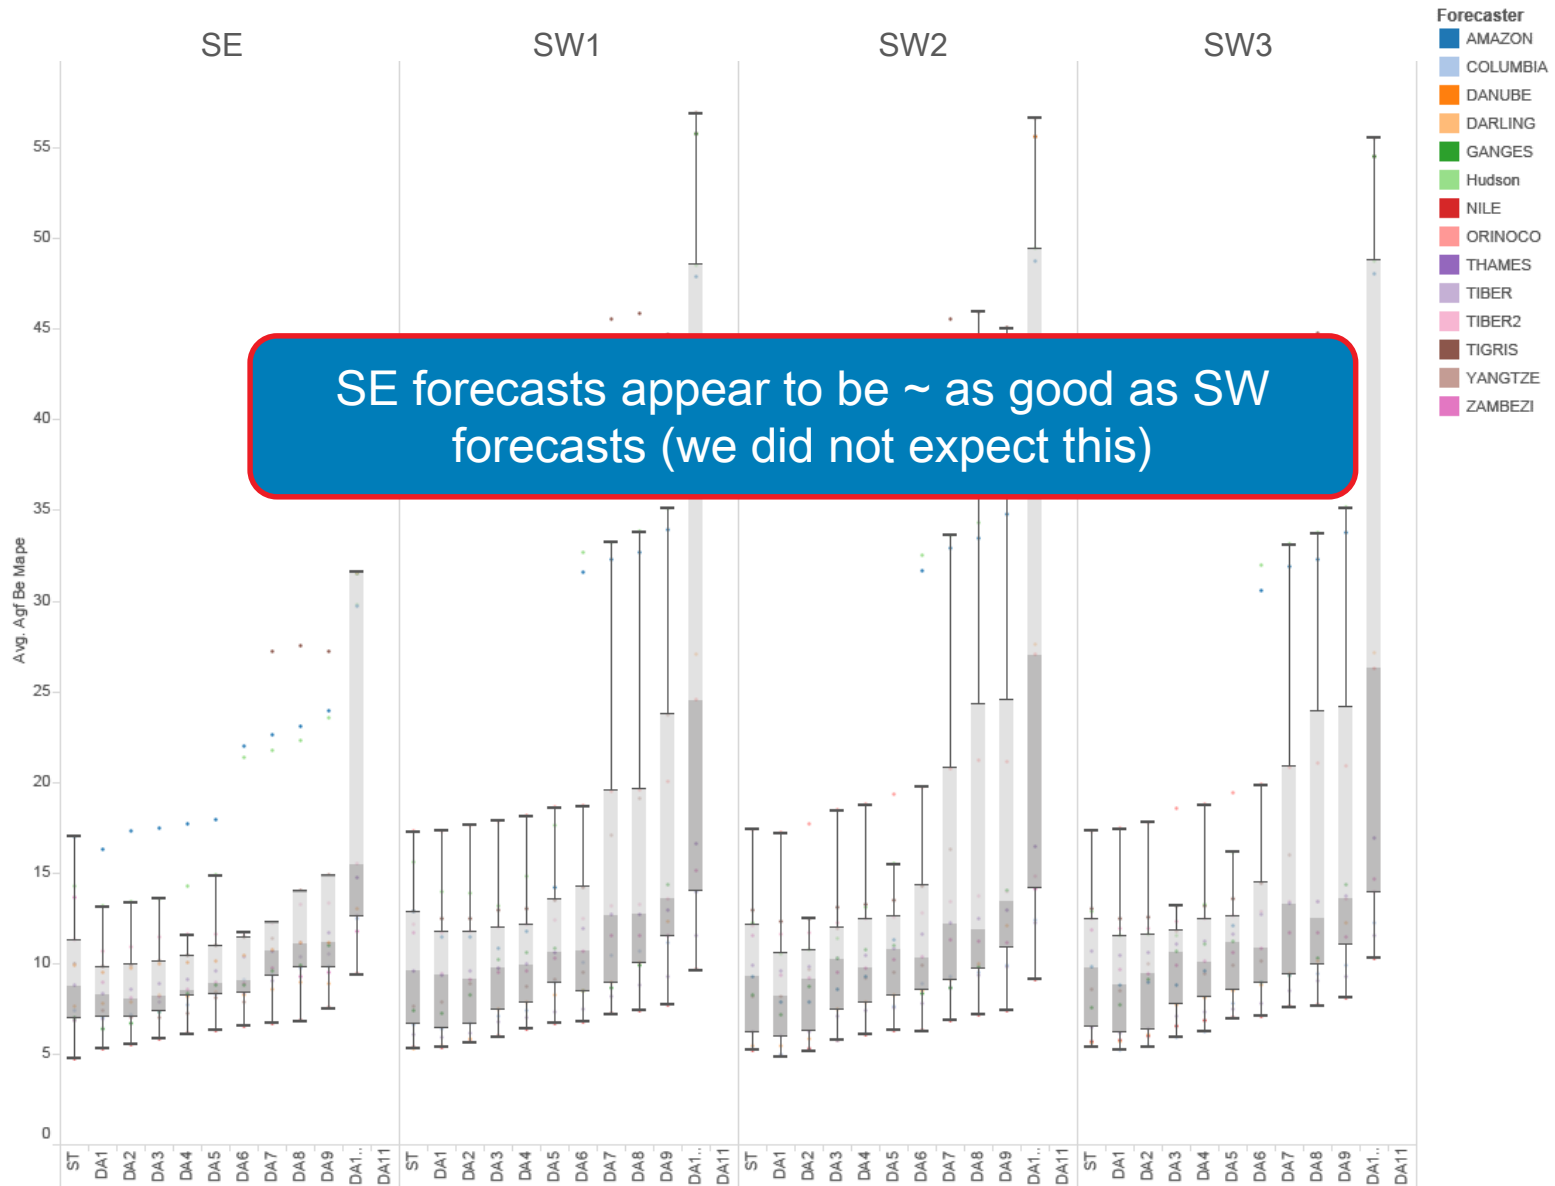

Cumulative FSI (SE site)

Zambezi baseline is close to the skill of better forecasts (after adjusting for outages)

MAPE by horizon (all forecasts)

Cumulative MAPE Wins

(Initial) Conclusions

- “Best” forecast is hard to define (Everyone already knew this)
- A forecast needs to be more than just reasonably accurate to be valuable
- SE forecasts may be as good as SW forecasts

Thanks to...

- ...EPRI for project management and analysis
(Aidan Tuohy, Eamonn Lannoye, and others)
- ...University of Arizona for PVLIB work (Will Holmgren)
- ...Vendors for participation
