Markets Shape Storage Deployment

Historical Battery Deployment in ERCOT & CAISO

Battery deployment in **ERCOT** and **CAISO** is due to high amounts of variable generation, along with enhanced market designs

Sources and Notes: Figure reformatted from results in CAISO 2022 Special Report on Battery Storage Resources and from Modo Energy.

Markets Distinctly Enable Storage Revenues

**Unlocking Storage Value
Across Energy, Ancillary
Service, and Capacity
Markets**

Sources and Notes: Figure reformatted from results in CAISO 2022 [Special Report](#) on Battery Storage Resources and from [Modo Energy](#). In 2022, batteries in CAISO received nearly \$30.5 million of bid cost recovery (BCR) mostly from RT market (~10% of all BCR settled despite being 5% of ICAP). Energy category includes revenues from Imbalance schedules. CA RA contract revenue ranging from \$60 - \$96 /kW-year is from Figure 16 (“RA only”) CPUC 2023 [Energy Storage Procurement Study](#).

(\$/kW-yr) 2022 Storage Revenue from RTO Markets

Limits of Conventional Market Design

Growing Reliance on Variable Resources Across the Country Will Increase Flexibility Needs Beyond the Limits of Current Market Design

The Challenge:

- Load growth + retirements raise resource adequacy needs
- Increased reliance on variable resources (with fewer dispatchable fossil units) create flexibility needs

Storage can meet these challenges, but storage value is constrained by market designs that do not currently address all system needs, nor fully accommodate the special capabilities (and limitations) of storage resources

Key Market Design Elements to Leverage Storage Capabilities

	Conventional Grid	Emerging Clean Grid Enabled by Storage
Dominant Capabilities 	• Slow ramping conventional generators • High startup cost/time • Difficult installation in limited sites	• Fast ramping inverter-based resources • Always available • Storage installs quickly and in many places
Market Interaction 	Economics dominated by fuel costs/fuel availability of traditional resources	Volatile high and low prices, storage economics dominated by limited energy and opportunity costs of electricity
Grid Needs 	• Modest uncertainty and ramp • Simpler peak-load capacity needs • Legacy units integrated into transmission planning	• Increase in renewables increases the value of flexibility and RA needs change • Retirement of legacy generators creates new Tx challenges and opportunities

Missing Market Functions

New flexibility products

Energy market bidding rules allowing opportunity cost and faster bid updates

Capacity market based on hourly reliability

Better retirement planning

1

Ancillary Service Market Reform: Intrahour Ramp/Uncertainty Product with Operating Reserve Demand Curves

Impact Potential

- Transparent price to meet growing reliability need for flexibility
- Reduce uneconomic thermal cycling
- Reduce unnecessary renewable curtailment

Concept: Dispatch at t_0 meets net demand at $t+5$ and procures flexibility to ensure system can ramp to net demand at $t+15$

	SPP	CAISO	NYISO	MISO	PJM
Implemented?	✓	✓	Proposed (Uncertainty only)	✓	Stakeholder process

Ancillary Service Market Reform: Day-Ahead Uncertainty Product with Operating Reserve Demand Curve

Value of flexibility increasing rapidly, but markets lack a product that captures this system need

Impact Potential

- Replaces out-of-market actions with transparent price signals for availability of dispatchable resources
- Can improve efficiency and reliability via more systematic procurement of availability beyond day-ahead energy commitments

pending

(DA Uncertainty only)

Stakeholder
Process

Opportunity cost bidding is optimal, but not allowed everywhere

Impact Potential

- **Increased Reliability** – storage incented to be available during peak demand or scarcity
- **Enhanced Market Efficiency** – true offer costs reflected
- **Greater Flexibility** – storage can more effectively provide energy, reserves, frequency regulation
- **Revenue Clarity** for storage operators, encourages efficient investment

Alternative Reliability Solutions after Retirement: Meeting Needs the Market has Failed to Address

Impact Potential

Post-retirement reliability needs can be addressed with transmission, supply resources, or other non-wires solutions; selecting the most cost-effective solution from a broad array of options lowers bills and facilitates quicker adaption to transition

Capacity Market Reform: Accurate Storage Dispatch in Reliability Modeling

Scope: assess two previously identified topics that underestimate storage capacity value without otherwise addressing core risk modeling

Topic 1: Change Simulated Storage Dispatch

- Marginal ELCC/MRI methods evaluate the impact of incremental additions of a resource with 3 simulation scenarios (baseline, with test resource, and with benchmark resource)
- Unlike PJM and NYISO, MISO uses a less accurate one-step heuristic method that does not evaluate incremental additions; it instead looks only at the base scenario, leading to underestimation of storage capacity value

Topic 2: Change Dispatch Order in Reliability Models

- Reliability models simulate stressed system conditions in which storage is exhausted after discharging for many hours
- If storage is dispatched before emergency procedures in the simulation (counter to actual operations in some cases), it experiences more resource exhaustion before risk hours, reducing the reliability value that storage otherwise could provide
- Furthermore, the dispatch order of similar energy-limited resources, (e.g. Demand Response) has substantial impact on capacity value

Market Design for Energy Storage: Summary of Key Reforms

Proposed Market Reform	How Reform Improves Reliability
Ramp and uncertainty product: managing fast, short-term changes in net load	Manages fast, short-term fluctuations in net demand. By smoothing fluctuations, storage avoids unnecessary renewable curtailment and supports base generation by preventing inefficient ramping
Day-Ahead Uncertainty Product: ensuring resources are positioned for expected hourly changes in load	Ensures sufficient resources are available on the next day to meet net demand forecasts, including a margin for uncertainty. Storage meets these needs at low cost, and reduces the burden on traditional steam generators that incur substantial start-up costs. Procures greater flexibility to the grid to accommodate low-cost renewable generation
Opportunity Cost Bidding: ensuring storage can provide optimal reliability and efficiency benefits through pricing and real-time market participation	Enables storage to strategically charge when electricity is cheapest and discharge during highest-value periods of peak demand, maximizing reliability benefits and market efficiency. Improves price signals, reduces inefficient cycling of traditional generation, promotes stable pricing, overall lowers system costs
Contracting for local reliability needs after retirements: an alternative to costly Resource-Must-Run contracts and transmission upgrades	Competitive alternative to costly Reliability-Must-Run contracts (which keep uneconomic plants online) and transmission upgrades (which may take years). Can lower costs for ratepayers and enhance system reliability.
Accurate capacity accreditation: for energy storage and all resources ensures capacity ratings match real capability	Accurately valuing storage peak capacity contributions ensures the grid can quickly deploy all resources to meet growing reliability challenges of load growth, maintain most cost-effective mix of resources, reduce the risk of outages, enhance system resilience
